ABSTRACT

The most common clinical causes of metallic foreign body in the breast are surgical clips, pieces of guide-wire and gunshot wounds. Metallic foreign bodies can lead to local breast pain, abscesses, pneumothorax after granulomas or migration, and cardiac tamponade. Mammotome biopsy, fluoroscopy, guide-wire biopsy and radio-guided occult lesion localization (ROLL) are the standard techniques applied for surgical excision of non-palpable breast lesions. This article presents the second case in the literature undergoing the ROLL technique for the removal of a metallic foreign body from the breast.

Keywords: Breast, gunshot injury, metallic body, mammography

Introduction

Metallic foreign bodies (MFB) within the breast develop out of surgical clips, broken pieces of guide-wires and gunshot injuries (GSI) (1). As such, metallic foreign bodies can cause local breast pain, abscess, cardiac tamponade, granuloma or pneumothorax, which are clinically significant (1-2). In this report, we aim to present a 35-year-old female patient diagnosed with a metallic foreign body in the left breast as the second case in the literature in which radio-guided occult lesion localization (ROLL) was used for the excision of the foreign body.

Case Presentation

A 35-year-old female patient presented to the general surgery department with pain in the left breast. She had a history of a gunshot wound in the breast four months ago, shortly after which the symptoms had started. The patient told that the bullet was still in her breast. Physical examination revealed tenderness in the upper outer quadrant of the left breast. The breast ultrasound indicated a 10 mm hyperechoic formation in the upper outer quadrant of the left breast. The mammography and chest x-ray confirmed the presence of a 10 mm hyperdense MFB within the breast. The object was not fragmented (Figure 1-2). It was decided to surgically remove the foreign body and written informed consent from the patient was obtained. On the morning of surgery, the MFB was marked using the ROLL technique in the radiology unit. The foreign body was excised along with the surrounding fibrosis and inflammatory breast tissue by applying a gamma probe through a 3 cm incision in a 20-minute operation. Specimen mammography was performed on the excision material to confirm that the MFB was located within the tissue (Figure 3).

Discussion and Conclusion

Since metallic foreign bodies can cause symptoms such as local breast pain, abscess, cardiac tamponade, granuloma or pneumothorax, they have clinical importance (1-2). Korbin et al. (3) reported broken guide-wire pieces in 5 of 3500 patients who underwent guide-wire biopsy. Monterey et al. (4) reported that the most common types of MFB in the breast are surgical clips and broken pieces of guide-wires. In that same study, the prevalence of MFB related to broken guide-wire pieces was found to be 0.2%. As reported in several studies addressing MFB in the breast, surgical clips, pieces of guide-wires and GSIs are the most common factors in etiology. Mammography is usually helpful for the diagnosis (1, 2, 5). In our case, the patient had a history of GSI as well as pain in the left breast as consistent with the literature. The MFB was clearly visualised in ultrasound, mammography and chest x-ray.
Metallic foreign bodies within the breast are treated through surgical excision. Guide-wire, fluoroscopy, mammotome biopsy and ROLL are the guiding techniques reported in the literature for non-palpable MFBs (1, 2, 4-6). The ROLL technique was first introduced in 1996 and has since been successfully applied for various cases including non-palpable breast lesions, parathyroid adenoma, recurrent papillary thyroid cancer and extraction of MFBs from the breast (5, 7, 8, 9).

In conclusion, considering the advantages it offers such as three-dimensional localization, smallness of incision, reduced aesthetic concern, shortened duration of operation and hospitalization and reduced cost, the ROLL technique can be conveniently used for extracting non-palpable organic, inorganic and metallic foreign bodies from the breast.
